Background Information

IFFO1, also named as IFFO and Tumor antigen HOM-TES-103, is a member of the intermediate filament family which consists of primordial components of the cytoskeleton and nuclear envelope that are mainly distributed in the nucleus, followed by the cytoskeleton and cytoplasm. IFFO1 in the nucleus was identified to combine with both XRCC4 and the nuclear lamina protein lamin A/C to be involved in nonhomologous DNA end joining (NHEJ). The expression of IFFO1 is associated with tumor progression. IFFO1 could be used as a potential marker to differentiate malignant ascites cell-free tumor DNA (cftDNA) of ovarian cancer from benign controls.
