Background

Clathrin is the major protein of the polyhedral coat of coated pits and vesicles which entrap specific macromolecules during receptor-mediated endocytosis. The clathrin molecule has a triskelion shape. Each clathrin triskelion is composed of three identical heavy chains and three light chains of two types, LCA (CLTA) and LCB (CLTB). The light chain subunits are thought to regulate the formation or disassembly of clathrin coats.

Synonyms

Clathrin light chain B, clathrin, light chain (Lcb), CLTB, LCB
